TITLE: An ultrasonic method of testing operating liquids of hydrosystems to destruction

SOURCE: Zavodskaya laboratoriya, v. 30, no. 10, 1964, 1239-1241

TOPIC TAGS: ultrasonics, hydrosystem, hydraulic system, stability, kinematic viscosity, cavitation/ 4770 radiation generator

ABSTRACT: The authors proposed an ultrasonic means of determining the stability of the functional liquids in a hydraulic system. It was decided that cavitation was the deciding factor in the ultrasonic destruction of a polymer molecule. Tests with a frequency of 500 kilocycles indicated no loss in liquid viscosity up to the point of cavitation. In the current tests ultrasonic frequencies of 18-22 kilocycles were used for 1.5 hours upon a variety of inhibitors and lubricants. The test liquids flowed through a glass container in which they were exposed to ultrasonic vibration from a type 4770 machine. Liquid destruction was determined by a drop in the kinematic viscosity as measured by a capillary viscosimeter. Results indicate that the effect of viscosity drop depends upon the irradiation time and upon the volume of test liquid. These results were tabulated for 5 test liquids and were

TITLE:

Orientation of Adsorbed Molecules in the Monomolecular Layer
on Oxidizing Catalysts (Ob oriyentatsii adsorbirovannykh molekul
v monomolekulyarnom sloye na okisnykh katalizatorakh)

PERIODICAL:

Izvestiya Akademii nauk SSSR. Otdeleniye khimicheskikh nauk,
1959, Nr 2, pp 363-365 (USSR)

ABSTRACT:

In the present paper the authors investigated the adsorption of the lowest saturated alcohols, from C₁ to C₄, of n-pentane and dichloro ethane by differently produced Al₂O₃-samples and MgO-, ThO₂- and ZnO-catalysts. From the determinations of the adsorption isothermal lines at 25° it was seen that the adsorption in the monomolecular layer is decreasing in the following order: CH₃OH > C₂H₅OH > n-C₃H₇OH > n-C₄H₉OH > i-C₃H₇OH = i-C₄H₉OH > s-C₄H₉OH > t-C₄H₉OH. The size of the elementary places occupied by the adsorbed alcohol molecules on the surface depends both on the structure of the alcohol and on the catalyst. It was assumed that at moderate temperature

Card 1/2

SOV/62-59-2-34/40

Orientation of Adsorbed Molecules in the Monomolecular Layer on Oxidizing Catalysts

there is also a plane orientation in addition to the normal one of the adsorbed molecules (hydroxyl groups are oriented towards the surface). The portion of planely oriented molecules is different for various alcohols and catalysts. For this reason it is advisable to introduce instead of the actual size of the elementary place a new term, the "effective specific place" σ_{eff} . It depends on the numerical ratio of the planely and parallelly adsorbed molecules and is different for one and the same alcohol on various catalysts. The variation of the chemical character of the catalyst considerably affects the σ_{eff} . (Table). There are 1 table and 9 references, 6 of which are Soviet.

Title:

A SPECTRAL METHOD FOR DETERMINING GAMMA-RAY DOSES

Periodical:
Referativnyy zhurnal, Mashinostroyeniye, no. 5, 1962, 64 abstract 32.5.356 (*Trudy in-tov Kom-ta standartov, mer i izmerit priborov pri Sov. Min. SSSR*, no. 55(115), 1961, 90-98)

Text: Description is given of a method for determining radiation doses from flat β -sources, the method being based on the use of an active electron spectrum. Spectral research was carried out by means of a scintillation beta-spectrometer consisting of a 1-C photomultiplier and a stilbene crystal 20 mm long and 25 mm in diameter. During the measurements the spectrometer and radiation source were enclosed in a nontranslucent (opaque) container. The efficiency of the measuring unit was determined by comparing the measurement results obtained by the same source and by a 4π counter. Comparison was made of the intensity values of the absorbed dose, by measuring both with the ionization (extrapolation) and the scintillation chambers. When using a Tl^{204} source with a working diameter of 38 mm, the intensity values of the dose measured by the above methods at a distance of 9 cm from the source, showed good agreement, with a deviation of only $\pm 2.5\%$. The distribution of the dose field was investigated for a series of beta radiators (S^{35} , Tl^{204} , Y^{90} and U^{231}) of varying working diameter, applied to different supports. In these experiments, the scintillation counter was

Card 1/2

A SPECTRAL METHOD.

5263 62 000 005 007 015
1007 1207

located above the center of the source; the distance between the lower surfaces of the crystal and the source surface varied from 2 to 11 cm. The paper gives the variation of the dose intensity both with distance and thickness of the filter (for Tl²⁰⁴ and Y⁹⁰ sources). The tests ensured an exponential variation of the dose intensity with the distance and the thickness of the filter. Values were obtained for average doses of S³⁵, Tl²⁰⁴ and Y⁹⁰ sources calculated to one beta particle, the dependence of the average dose calculated to one beta particle, on the maximum energy of the beta spectrum, was shown graphically. The dependence of the dose as a function of the source shape was stressed upon and the error in determining the dose intensity by scintillation methods was estimated. Thus, the maximum error was found to be $\pm 20\%$. There are 9 figures and 9 references.

TITLE: Effect of the degree of dehydration of the Al_2O_3 surface
on its adsorptive properties and on the elementary area
of the molecules adsorbed

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Otdeleniye
khimicheskikh nauk, no. 1, 1963, 17-21

TEXT: The elementary area ω populated by an adsorbed Ar atom or N_2 ,
 $\text{C}_2\text{H}_5\text{OH}$, n-C₅H₁₂ or C₆H₁₂ molecules was determined in Al_2O_3 samples
calcined at 300°C (sample I) up to 1000°C (sample IV). The adsorption of
Ar and N_2 was measured at -195°C, that of the organic compounds at 25°C.
 ω_{Ar} was assumed constant at all temperatures and equal to 16.6 \AA^2 . \AA^2 -
values found for sample I: $\omega_{\text{N}_2} = 17.2$; $\omega_{\text{C}_2\text{H}_5\text{OH}} = 28.2$; $\omega_{\text{n-C}_5\text{H}_{12}} = 54.2$;

Card 1/3

S/062/63/000/001/003/025
B101/B186

Effect of the degree of ...

$\omega_{C_6H_{12}}$ = 54.5; for sample IV: 15; 24.3; 46.5 and 44.5, respectively.

ω_{N_2} was almost constant for all Al_2O_3 samples heated to more than $300^{\circ}C$.

Conclusions: The determination of the specific area of Al_2O_3 catalysts by N_2 adsorption is not affected by the degree of surface dehydration.

The slight changes of $\omega_{C_2H_5OH}$ do not explain the previously observed

(Zh. fiz. khimii, 35, 858 (1961)) large differences of ω when alcohol was adsorbed on Al_2O_3 samples of various origin, which were dehydrated at $500^{\circ}C$. The reduction of $\omega_{C_2H_5OH}$ with increasing dehydration may be

explained by formation of highly active oxygen bridges between the aluminum atoms in intensely calcined samples. The ω of the two hydrocarbons varies between physical values. The anomalous increase of ω observed by M. M. Dubinin (Izv. AN SSSR, Otd. khim. n. 1960, 1739) in fluorized silicagels was not observed with Al_2O_3 , although interaction

Card 2/3

Effect of the degree of ...

S/062/63/000/001/003/025

between the molecules of the adsorbate is equally possible. Hence, the BET (Brunnauer, Emmett, and Teller) equations can be used for Al_2O_3 as its surface is only slightly inhomogeneous. There are 1 figure and 2 tables. The most important English-language reference is: I. B. Peri, R. B. Hannan, J. Phys. Chem., 64, 1526 (1960).

Title : Investigation of Alloys of the Gold-Cobalt System

Orig Pub : Zh. neorgan. khimii, 1956, 1, No 5, 1047-1051

Abstract : The microstructure, hardness, electric resistivity, and temperature coefficient of electric resistivity of Au-Co alloys were studied. The initial materials were 99.99% gold and cobalt containing approximately 0.01% carbon. The resulting diagram of state is good agreement with data of other investigators. Increasing the Co content results in a linear increase in the hardness of the alloys in the two-phase region, reaching 145 kg/mm² at 98% Co. In the solid-solution region, the hardness drops off towards the pure components, sharply towards Au, and less sharply towards Co. The electric resistivity of the alloys first increases as Co is added, and then varies almost linearly with a slight reduction towards Co. The temperature coefficient of the electric resistivity varies also almost linearly in the two-phase region, and increases with increasing content of Co.

Title : Investigation of the Palladium-gold-Cobalt System
Orig Pub : Zh. neorgan. khimii, 1956, 1, No 5, 1052-1063
Abstract : Thermal-analysis methods and studies of the hardness and the microstructure after annealing and hardening from different temperatures, of the specific electric resistivity, and of its temperature coefficients were all used for the first time to study the Pd-Au-Co triple system. The two-Phase region in the gold-cobalt system spreads extensively into the triple region, which reaches up to 47% Pd at the center of the diagram at room temperature, and is gradually reduced with increasing temperature, reaching 35% Pd at 1000°. The double-eutectic line starts out from the eutectic field of the Au-Co system and extends into the triple system until it reaches a section with 20% Pd. The remaining portion of

On Polymorphous Transformations of Chromium in Alloys With
Tantalum

PERIODICAL:

Zhurnal neorganicheskoy khimii, 1959, Vol 4, Nr 9, pp 2168-2169
(USSR)

ABSTRACT:

The cooling curve for liquid chromium determined by N. A. Nedumov (Ref 4) exhibits, in the vicinity of the very distinct maximum corresponding to the crystallization temperature, a second maximum which relates to the transition of chromium into another modification at 1815°. By means of microscopic, thermal, and X-ray analyses the chromium-tantalum alloy was investigated in the range rich in chromium after hardening; The location of the solidus and the limits of solubility of Ta in Cr were checked. 1830° was found to be the temperature of transition between the modifications ϵ and δ . In contrast with the data obtained by N. Grant (Refs 1, 2) it was found that immediately after freezing chromium does not possess a face-centered but a cubic body-centered

TITLE:
High-Temperature Modifications of Chromium and the Phase
Diagram of the System Chromium - Niobium in the Region
Rich in Chromium
2

PERIODICAL:
Fizika Metallov i Metallovedeniye. Series 2, Khimika, 1960,
No. 4, pp. 25 - 24

TEXT:
A study of the binary system chromium - niobium (up to 22 wt% Nb) shows that due to the phase transformations of chromium there exist four series of mixed crystal formation and three two-phase zones (Fig. 2), having basic origin in the transformation points of chromium: 1830°C (α → β), 1650°C (α → γ), and 1500°C (γ → β). These transformations points are also found on the heating and cooling curves of chromium iodide (Fig. 1). X-ray analysis of the chilled samples gave the following results: The α-addition phase is a body-centered cubic crystal with $a = 2.867 \pm 3$ Å; the δ-addition is hexagonal, and for 1550°C it has the constants $a = 2.756 \pm 5$ Å and

Card 1/2

$a/\sqrt{a} = 1.001$; the γ-phase is a body-centered cubic crystal with lattice constants similar to the δ-phase; the β-modification is probably a face-centered cubic crystal. Results obtained from studies of the systems Cr-Mo, Cr-Mn, Cr-Ni, Cr-Fe, Cr-Fe-Si, and Cr-Co-Mn were communicated to the International Conference on Metallurgy and Allotropy in April 1958, and (Conference on Heat-resistant Metals and Alloys) in April 1960, as well as to the VII Mandel'skiy Congress (8th Mandel'skiy Congress) in March 1959. There are 2 figures and 2 non-Dosite references.

TITLE:

Investigation of Alloys of the Palladium - Silver - Chromium System

PERIODICAL:

Zhurnal neorganicheskoy khimii, 1960, Vol 5, Nr 4, pp 894 - 901
(USSR)

ABSTRACT:

The authors briefly refer to data available in publications on the binary systems Pd - Ag, Ag - Cr, and Pd - Cr and in this connection mention Ye. Ya. Rode (Ref 3), V. G. Kuznetsov (Ref 4), V. A. Nemilov et al. (Ref 5), and A. T. Grigor'yev et al. (Ref 7). To investigate the phase diagram of the ternary system Pd - Ag - Cr alloys of seven sections were prepared with a palladium content between 20 and 80% increasing by 10% each time. Furthermore, the sections with 35.65 and 75% palladium were investigated. Thermal analysis was made by means of an N. S. Kurnakov recording pyrometer. The results are given in table 1 and illustrated in figure 2. The hardness test was carried out by impressing a steel ball of a diameter of 10 mm with a load of 250 kg into the annealed specimens (Table 2, Fig 3). The microstructure (Figs 4,5) was investigated on samples etched by an alcoholic bromine solution. Electrical resistance at

Card 1/2

69024

Investigation of Alloys of the Palladium - Silver - Chromium System 8/076/60/005/04/021/040
B004/B016

25 and 100° was determined by the potentiometric method (Table 1, Fig 6). Therefrom the temperature coefficient of electrical resistance was calculated (Table 1, Fig 7). On the basis of the resultant data the phase diagram (Fig 1) was plotted. The region of decomposition occurring in the Ag - Cr system likewise exists in the ternary system and reaches up to about 42% Pd. The largest part of the diagram consists of a region of mechanical mixing. A eutectic point is assumed to be near the Ag in the Ag - Cr system, which is connected with the eutectic point of the Pd - Cr system by the line of the double eutectic. Part of the diagram in the palladium corner consists of a solid solution resulting from the binary system Pd - Cr and adjoining the system Pd - Ag as a narrow zone. There are 7 figures, 2 tables, and 9 references, 4 of which are Soviet.

TITLE:

Investigation of Alloys in the System Palladium - Copper - Chromium

PERIODICAL: Zhurnal neorganicheskoy khimii, 1960, Vol. 5, No. 5, pp. 1112-1118

TEXT: In the introduction the authors give a survey of publications dealing with the binary component systems of the ternary system Pd - Cu - Cr. They refer to papers by V. A. Nemilov et al. (Ref. 12) and A. A. Rudnitskiy (Ref. 13). Fig. 1 gives the phase diagrams of the binary systems (adjacent to the resultant diagram of the ternary system). The ternary system was investigated in nine sections with a Pd content of between 10 - 90 wt% Pd increasing by 10% each time. The thermal analysis was made by means of an N. S. Kurnakov pyrometer (Fig. 2). Further the microstructure of the alloys was investigated, which were annealed at 800-1,000° and hardened, as well as etched with alcoholic bromine solution (Figs. 3, 4). Their Brinell hardness was determined (Fig. 5), the electric resistance measured at 25° and 100° (Fig. 6), and its temperature coefficient determined (Fig. 7). The experimental data are also summarized in a table. The phase diagram is given in Fig. 1. The range of disintegration in the liquid state, which is observable in the system Cu-Cr, is also maintained in the phase diagram of the ternary system

and reaches up to 35% Pd. The major part of the diagram is occupied by a mechanical mixture with a binary eutectic line which connects the eutectic points of the systems Cu-Cr and Pd-Cr. In the Pd corner there is a range of solid solution which originates from the system Pd-Cr and is adjacent to the system Pd-Cu as a narrow strip. The range of solid solution increases with increasing temperature. There are 7 figures, 1 table, and 14 references, 3 of which are Soviet.

TITLE:

Polymorphous Conversions of Chromium in Alloys With Tantalum

PERIODICAL:

Zhurnal neorganicheskoy khimii, 1960, Vol. 5, No. 11,
pp. 2640-2642

TEXT: The authors have established in Refs. 1-5 that chromium appears in five modifications in its alloys. In addition to data from Refs. 1, 2, the present article presents the results of a study on the polymorphism of chromium in the constitution diagram Cr - Ta in the chromium-rich region. The specimens prepared in previous experiments (Refs. 1, 2) with 0.2 to 12 wt% Ta were examined. In doing so, the authors applied the thermal method by recording the heating and cooling curves on N. A. Nedumov's device, and the differential heating curves of annealed alloys (up to 1350°C) by a ПК-52 (PK-52) pyrometer. Microhardness was measured, and X-ray analyses were made. The constitution diagram (Fig. 1) was drawn on the basis of microstructural determinations (Fig. 2) and thermal analyses (Table). The

Diagram displays five regions of solid solutions formed by the α -, β -, γ -, δ -, and ϵ -modifications as well as four two-phase regions $\alpha+\beta$, $\beta+\gamma$, $\gamma+\delta$, and $\delta+\epsilon$ which proceed from the points of mutual transition of the chromium modifications: 1830°C ($\epsilon \leftrightarrow \delta$), 1650°C ($\delta \leftrightarrow \gamma$), about 1500°C ($\gamma \leftrightarrow \beta$), and about 930°C ($\beta \leftrightarrow \alpha$). Four eutectoid transformations were established in the region of the Cr - Ta constitution diagram at 1490°C , 1150°C , 950°C , and 775°C , which are caused by the eutectoid decomposition of the respective solid solutions. X-ray data of the individual phases agree with those yielded by previous investigations. There are 2 figures, 1 table, and 5 Soviet references.

TITLE: Polymorphous conversion of chromium and the phase diagram of
the system chromium - nickel in the range of concentrated
chromium

PERIODICAL: Zhurnal neorganicheskoy khimii, v. 6, no. 5, 1961,
1248 - 1251

TEXT: The alloys of chromium with nickel were studied in the range of
concentrated chromium by microscopic, thermal and X-ray analyses. Ther-
mal analyses were made by recording the heating and cooling curves of the
alloys hardened at 1200°C by means of a WK-52 (PK-52) pyrometer.
The phase diagram of the system chromium - nickel in the range of concen-
trated chromium was drawn on the basis of microstructural and thermal anal-
yses; it is schematically presented in Fig. 1. Five homogeneous ranges
of the solid solutions of α , β , γ , δ , and ϵ modifications of chromium

Polymorphous conversion of ...

were found which are separated by diphasic ranges $\alpha + \beta$, $\beta + \gamma$, $\gamma + \delta$, and $\delta + \epsilon$. Four eutectoid conversions occur at 850, 960, 1140, and 1220°C. X-ray analysis indicated that the solid solution ϵ of the alloy with 17% nickel has a body-centered cube with $a = 2.879 \pm 3$ kX. In the alloy with 13% nickel, hardened at 1400°C, with the solid solution $\epsilon + \delta$ the hexagonal lattice of the solid solution of δ with the parameters $a = 2.514$ kX, $c = 6.445$ kX, and $\frac{c}{a} = 1.62$ was found in addition to the body-centered cube of the solid solution of ϵ . The alloys with the phases $\alpha + \beta$ and β have a face-centered cube. Alloys with 17% nickel, hardened at 900°C and more, have a face-centered cube. The results obtained are in good agreement with the data in Refs. 1 - 6 (Ref. 1: A. T. Grigor'yev, L. N. Guseva, Ye. M. Sokolovskaya, M. V. Maksimova. Zh. neorgan. khimii, 4, 2168 (1959). Ref. 2: A. Polymorphous transformations...

representing solid solutions based on the ϵ , δ , and γ modifications of Cr were found to exist, together with the $\epsilon + \delta$ and $\gamma + \delta'$ two-phase regions; the $\epsilon + \delta$ region is associated with the $\epsilon \leftrightarrow \delta'$ transformation at 1830°C, while the $\gamma + \delta'$ is associated with the $\gamma \rightarrow \delta'$ transformation at 1650°. The simple ϵ phase occupies the region beneath the solidus curve, while the γ phase occupies the Cr-rich corner at temperatures below 1600°. An x-ray analysis of the 90% Cr alloy quenched from 1500°C showed that the ϵ -modification possesses a b.c.c. lattice with $a=2.878$ kX. There are 4 figures and 1 table.

TITLE: Nature of flash brightness in NaCl-Ni under light stimulation from F-band

SOURCE: Optika i spektroskopiya; sbornik statey. v. 1: Lyuminestsentsiya.
Moscow, Izd-vo AN SSSR, 1963, 198-202

TOPIC TAGS: phosphor, irradiation, M-center, recombination, optical flash

ABSTRACT: A study was made of the behavior of x-rayed NaCl-Ni phosphors under continuous and pulsed optical irradiation from the F-band. On the basis of data obtained a new interpretation is proposed of the Parfianovich effect (L. A. Parfianovich. Opt. i spektr. 2, 392, 1957). The experiment performed differed from that of Parfianovich in one respect only: the use of optical rather than thermal irradiation. It was found that under continuous F-center irradiation luminescence brightness diminishes irregularly with nickel concentration. Optical destruction of M-centers further diminishes the subsequent optical flashing, and heating the phosphor to 90-100°C after destruction of M-centers results in a sharp increase in optical flash brightness. The enhancement of flashing bright-

TITLE: Effect of added illumination in the F-band on the x-ray
luminescence of alkali-halide phosphors

SOURCE: Optika i spektroskopiya, v. 17, no. 5, 1964, 790-792

TOPIC TAGS: activated crystal, alkali halide, x ray luminescence,
F band, fluorescence quenching, light intensifier

ABSTRACT: The author investigated the effect of additional optical illumination in the F-band on the stationary luminescence of KCl(Tl) and KBr(Tl) excited with x-rays, as a function of the excitation temperature and of the activator concentration in the crystal. The x-ray excitation was from a tube with molybdenum anticathode (12 mA, 45 kV) and at the same time exposed to light in the absorption F-band, transmitted through different filters for the two crystals.

Card 1/3

L 1637-65
ACCESSION NR: AP4048756

The results indicate that F-stimulation under stationary conditions can, depending on the temperature of the experiment or on the concentration of the activator in the phosphor, either increase the probability of nonradiative recombination and quench the luminescence, or on the other increase the number of emission events and intensify the luminescence brightness. Depending on which of the two processes predominate, the total intensity will either increase or decrease. γ -stimulation causes emission of part of the light sum stored in the luminor, and in final analysis always quenches the luminescence. The light sum accumulates again after removal of the F-illumination. Although the present results do not actually refute earlier data (Ch. B. Lushchik et al, Tr. IFA AN ESSR, no. 15, 103, 1961) concerning an exciton mechanism for the transfer of energy from the crystal lattice to the luminescence centers, they do show that the method proposed by Lushchik et al. to prove this transfer is not sufficiently well founded. Orig. art. has: 2 figures.

ABSTRACT: The authors have investigated the effect of pulsed illumination with F band radiation on the x-ray excited phosphorescence of a number of alkali halide phosphors. Different effects were observed, depending on the phosphor. In KCl:Tl, NaCl:Tl, KCl:Ag, NaCl:Ag, KBr:Ag, and NaBr:Ag, illumination with a flash of F band radiation increased the intensity of the phosphorescence. In KCl:Tl the intensity of this secondary phosphorescence decreased as the primary phosphorescence decayed, i.e., the weaker the primary phosphorescence at the time of illumination with F band radiation, the weaker the secondary phosphorescence; in NaCl:Tl it did not. In KBr:Tl and KBr:In the F band radiation quenched the phosphorescence. In NaBr:Tl

and NaBr: In the F band radiation flash temporarily quenched the phosphorescence, i.e., the intensity of the primary phosphorescence decreased sharply and subsequently returned to its normal value. Possible explanations of all these effects are discussed briefly, but the authors refrain from advancing a final explanation until more experimental data become available. Orig. art. has: 3 figures.

TITLE: Investigation of thermoluminescence of x-irradiated alkali-halide phosphors

SOURCE: Optika i spektroskopiya, v. 18, no. 4, 1965, 637-643

TOPIC TAGS: thermoluminescence, alkali halide phosphor, recombination, x irradiation, activator center

ABSTRACT: The thermoluminescence and optical flashing were investigated under pulsed illumination in the F-band. It was found that the optical flash increases without time lag, and decreases in two stages, the slowly damped component (second-

without time lag, and decreases in two stages, the slowly damped component (secondary phosphorescence) lasting as much as 5 minutes. In KCl(Tl) this phosphorescence decreases with decreasing primary phosphorescence at room temperature. Subsequent heating causes it to rise and go through a maximum near +85°C, where a new thermoluminescence peak is observed, credited to V₂ centers. The phenomena observed are explained on the basis of the hole scheme of recombination luminescence, wherein the radiation of the light sum stored in alkali-halide phosphors following x-

irradiation is the result of recombination of holes with electrons localized in the activator luminescence centers. The phosphorescence observed immediately after excitation corresponds to thermal release of the holes from shallow levels and their recombination with atomic luminescence centers produced during the course of excitation. The thermoluminescence peaks correspond to release of electron-hole pairs from the capture levels and their recombination on the activator luminescence cen-
